Dyspepsia, Peptic Ulcer, and *H. pylori*: A Remembrance of Things Past

Nimish Vakil, MD, FACG¹

Abstract: Dyspepsia and gastroesophageal reflux disease are common conditions in clinical practice. Current management strategies emphasize testing and treatment for *Helicobacter pylori* in the initial management of patients presenting with dyspeptic symptoms in regions where the prevalence of *H. pylori* infection is >15%. Population-based studies in patients with dyspepsia suggest that peptic ulcer disease related to *H. pylori* infection is decreasing in prevalence, whereas gastroesophageal reflux disease is becoming a more common cause of dyspeptic symptoms. Unfortunately, symptoms are a poor predictor of endoscopic findings, and alarm features are not a good predictor of an underlying malignancy. Although peptic ulcer disease has declined in Western countries, specific populations

by evaluating patients in the general population who had not sought medical attention for their symptoms. In this issue of the Journal, Zagari *et al.* (1) report endoscopic findings in a population of subjects from two small Italian villages. This and several other studies provide interesting insights into the changing epidemiology of dyspepsia.

SYMPTOMS, PEPTIC ULCER DISEASE, AND ESOPHAGITIS

A recent meta-analysis of studies that evaluate the predictive value of symptoms suggests that physician assessments of symptoms do not predict whether an endoscopic lesion is found (2). The study by Zagari *et al.* also shows that symptoms are not a good predictor of the underlying endoscopic findings. Most dyspeptic patients have no significant abnormalities at endoscopy. The study by Zagari *et al.* shows that patients with predominant reflux symptoms have a higher prevalence of esophagitis, but peptic ulcer disease is less frequent.
